# Pathology of the stomach-part 2

Manar Hajeer, md, FRCPath

University of Jordan, School of medicine

- Most often is associated with H. pylori infection or NSAID use
- Imbalance between mucosal defenses and damaging forces.

- In USA, NSAID is becoming the most common cause of gastric ulcers: as H.*pylori* infection is falling and increased use of low-dose aspirin in aged population.
- Any portion of the GIT exposed to acidic gastric juices
- Most common in gastric antrum, first part of duodenum.
- Esophagus in (GERD) or ectopic gastric mucosa (Meckel diverticulum)

# **Pathogenesis**

- More than 70% of PUD cases are associated with H. pylori infection
- Only 5 -10% of H. pylori–infected individuals develop ulcers.
- Gastric acid is fundamental in pathogenesis.
- Cofactors: smoking, chronic NSAIDs, high-dose corticosteroids, alcoholic cirrhosis, COPD, CRF, hyperparathyroidism.
- Hyperacidity is caused by:
- H. pylori.
- Parietal cell hyperplasia.
- Excessive secretory response (vagal)
- Hypergastrinemia as in Zollinger-Ellison syndrome

## Zollinger-Ellison syndrome

- Multiple peptic ulcerations
- Stomach, duodenum, even jejunum
- Caused by uncontrolled release of gastrin by a tumor (gastrinoma) and the resulting massive acid production.

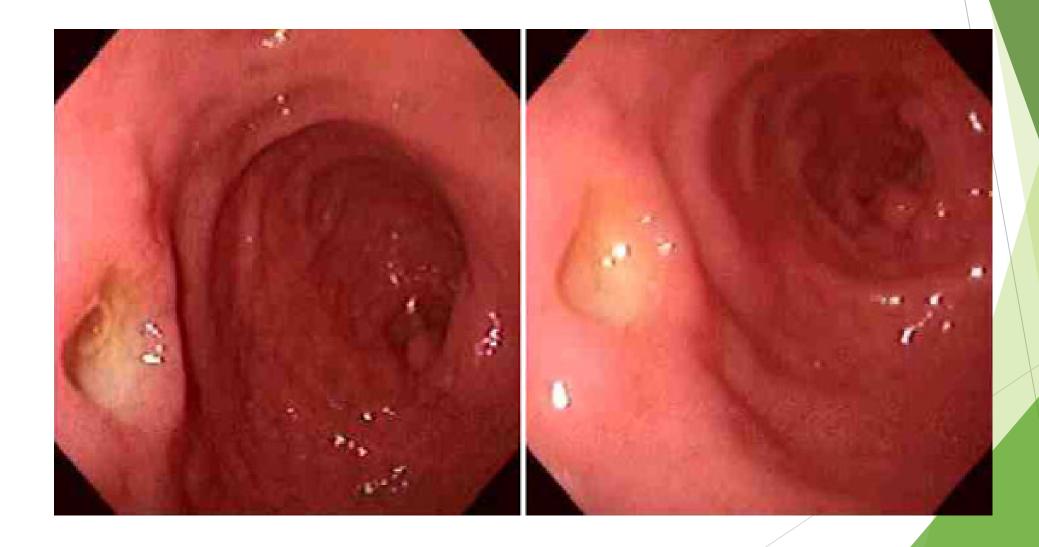

#### **MORPHOLOGY**

- 4:1, proximal duodenum : stomach.
- Anterior duodenal wall
- ► >80% solitary.
- Round to oval, sharply punched-out defect
- Base of ulcers is smooth and clean
- Granulation tissue.
- Hemorrhage & Perforation are complications.

# Duodenal ulcer

#### Clinical Features

- Epigastric burning or aching pain
- Pain 1 to 3 hours after meals at daytime
- Worse at night, relieved by alkali or food
- Nausea, vomiting, bloating, bletching.
- Iron deficiency anemia, frank hemorrhage, or perforation.
- Current therapies are aimed at H.pylori eradication.
- Surgery reserved for complications.

#### **GASTRIC POLYPS AND TUMORS**

- Gastric Polyps:
- Inflammatory and Hyperplastic Polyps
- Gastric Adenoma
- Gastric Adenocarcinoma
- intestinal and diffuse types
- Lymphoma
- MALToma.
- Neuroendocrine (Carcinoid) Tumor
- Gastrointestinal Stromal Tumor

# Gastric polyps

- Polyps: masses projecting above the level of adjacent mucosa
- Epithelial or stromal cell hyperplasia, inflammation, ectopia, or neoplasia.
- Inflammatory and Hyperplastic Polyps
- 75% of all polyps.
- Arise in a background of chronic gastritis
- Regress after H.pylori eradication.
- Risk of dysplasia if size > 1.5 cm.

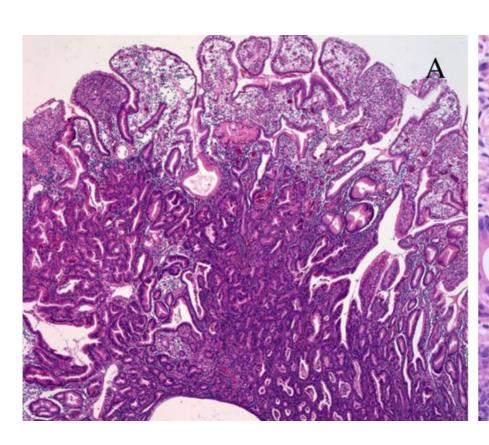

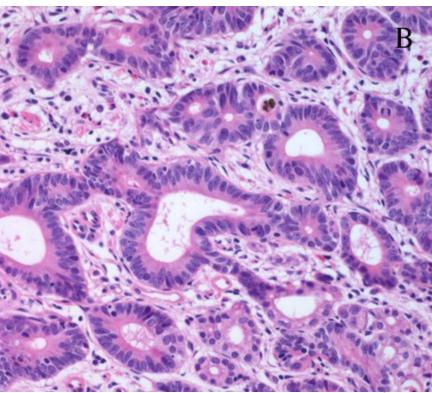

#### Gastric Adenoma

- ► 10% of all polyps.
- Increase with age.
- M:F = 3:1
- Background of chronic gastritis, atrophy and intestinal metaplasia.
- Dysplasia in all cases, low- or high-grade.
- Risk of adenocarcinoma related to the size (greatest if > 2cm).
- Risk of carcinoma higher than colonic adenoma.
- 30% have concurrent CA.

# Gastric adenoma

#### Gastric Adenocarcinoma

- 90% of all gastric cancers.
- Early symptoms mimic gastritis >>> late diagnosis.
- Rates vary markedly with geography (Japan, Costa Rica, Chile).
- Screening >> early detection.
- Background of mucosal atrophy and intestinal metaplasia.
- PUD does not increase risk, except after surgery
- ► In USA rates dropped > 85%, BUT increased rate of cardia cancer due to GERD & obesity.
- Two main types: intestinal and diffuse.

## Pathogenesis

- Genetic alterations due to H.pylori associated chronic gastritis, lesser extent EBV (10%).
- Most cases are sporadic.
- Familial cases: mutations in CDH1 (E-cadherin) >> diffuse type.
- Sporadic diffuse type Ca: CDH1 mutation in 50%.
- ► FAP: APC gene mutation, intestinal type cancer.
- Sporadic intestinal-type Ca: B catenin mutation
- P53 mutation in sporadic cancer of both types.

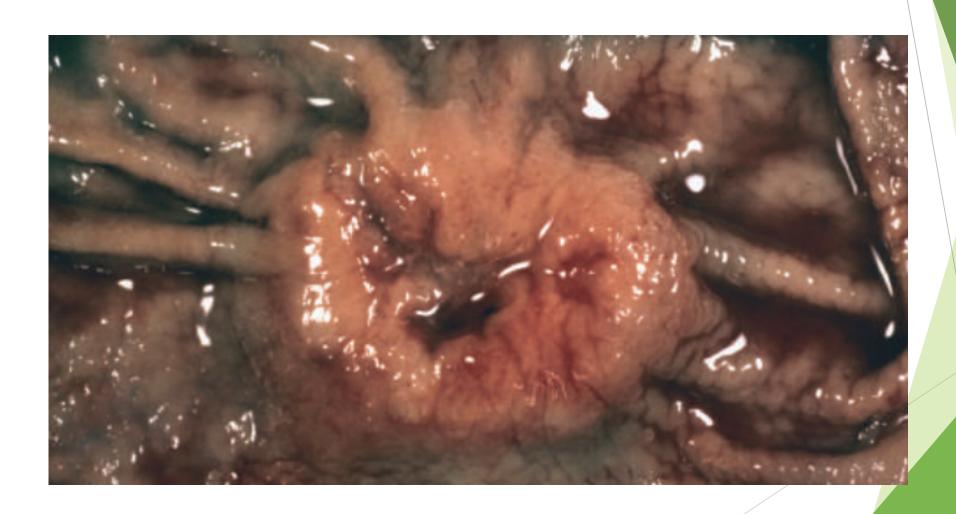

#### **MORPHOLOGY**

- Lauren classification: separates gastric cancers into intestinal and diffuse types.
- Intestinal type:
- Bulky.
- Exophytic mass or ulcer.
- Form glands.
- Diffuse gastric cancers
- Infiltrative growth pattern
- Discohesive cells (signet ring cells)
- Desmoplastic reaction (thick wall, linitis plastic).

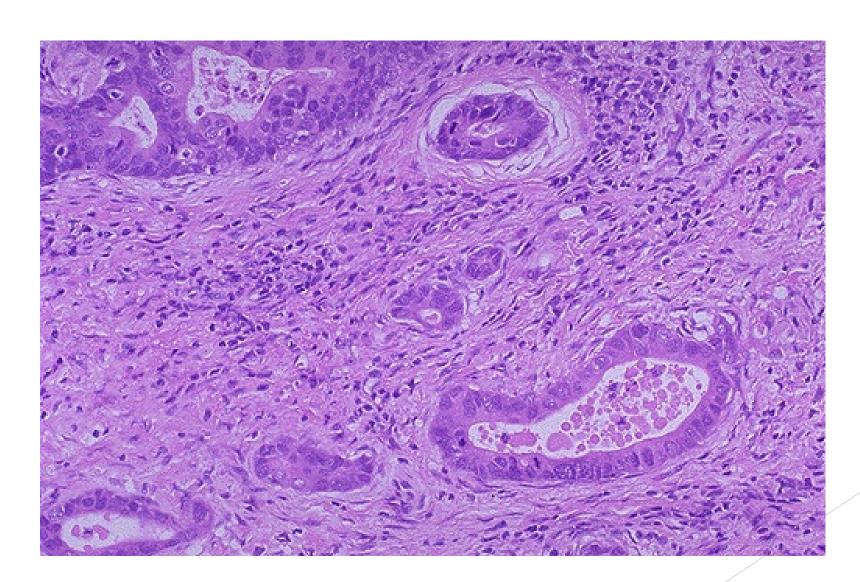

# Intestinal type

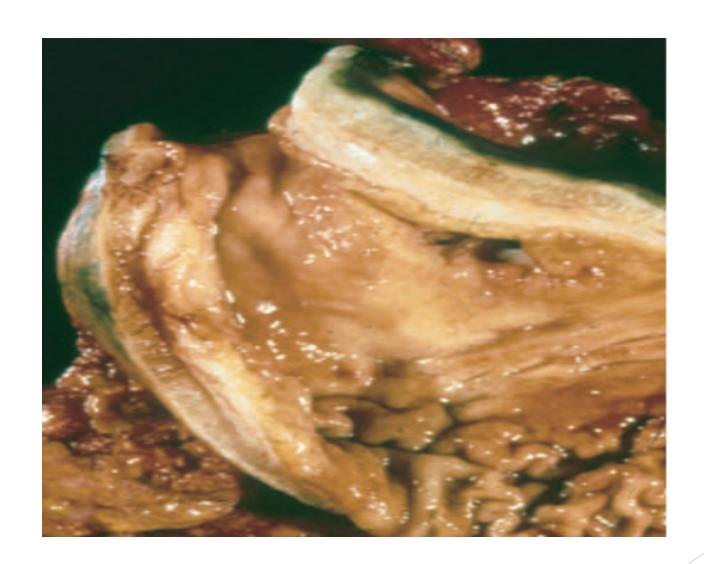

# Intestinal type

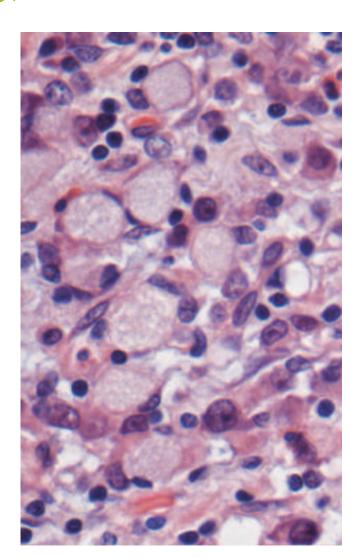

# Linitis plastica

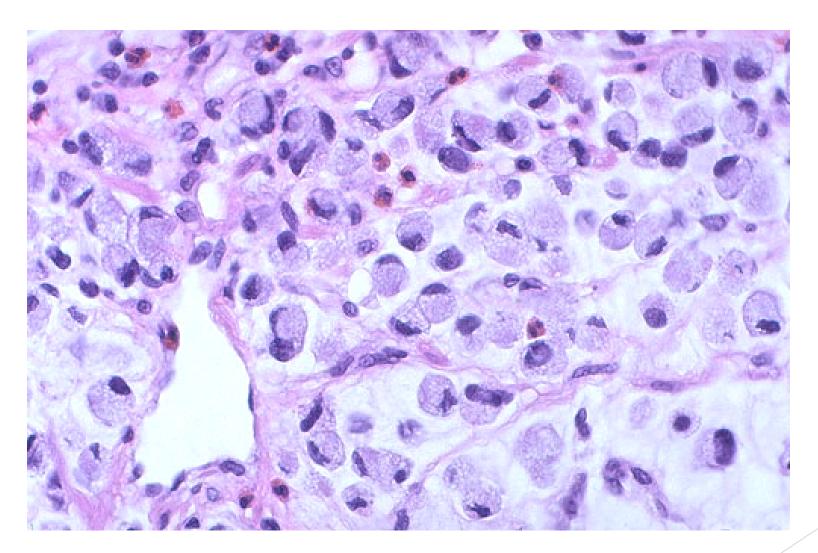

#### Signet ring cells:

large mucin vacuoles that expand the cytoplasm and push the nucleus to the periphery,

# Diffuse type, signet ring cells

#### Clinical Features

- Intestinal-type gastric cancer
- High-risk areas
- Develops from precursor (adenoma, dysplasia associated w/ intestinal metaplasia)
- Mean age 55 yrs.
- ► M:F 2:1
- Diffuse type gastric cancer:
- Incidence uniform across countries.
- No precursor lesion.
- ► M:F 1:1
- Younger age.

- Symptoms overlap with chronic gastritis, in addition to weight loss.
- ► The drop in gastric cancer incidence applies only to the intestinal type.
- Incidences of intestinal and diffuse types are now similar in some regions.
- Most powerful prognostic factors: depth of invasion & extent of nodal and distant metastasis at the time of diagnosis
- Most cases Dx at advanced stage.
- ► 5 year survival 90% to 20% for early and advanced tumors, respectively.
- Tx: surgery, chemotherapy, targeted Tx (anti HER2)

# Lymphoma

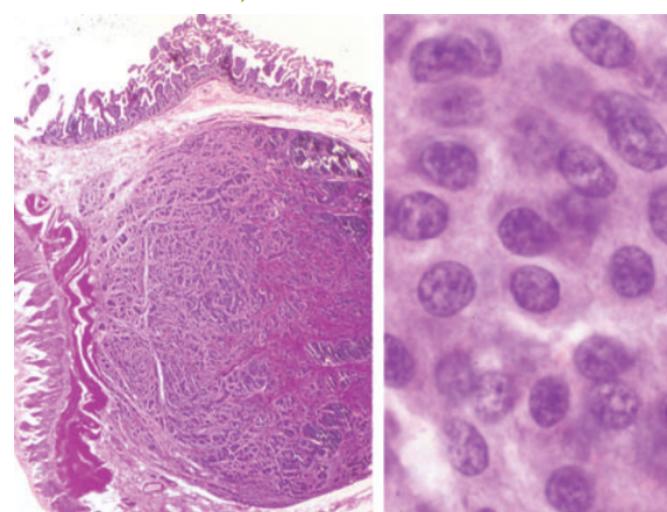

- Stomach is the most common site of extranodal lymphoma.
- 5% of all gastric malignancies.
- Most common type: indolent extranodal marginal zone Bcell lymphomas (MALToma)
- Second most common lymphoma: diffuse large B cell lymphoma

### Neuroendocrine (Carcinoid) Tumor

- Tumors arising from neuroendocrine-differentiated gastrointestinal epithelia (e.g., G cells).
- > 40% occur in the small intestine.
- Associated with endocrine cell hyperplasia, chronic atrophic gastritis, and Zollinger- Ellison syndrome
- Slower growing than carcinomas.

Intramural or submucosal masses (small polypoid lesions)

Islands, trabeculae, strands, glands, or sheets of uniform cells with scant, pink granular cytoplasm and salt and pepper chromatin.

## carcinoid syndrome

- Due to vasoactive substances
- Seen in 10% of cases.
- strongly associated with metastatic disease.
- Cutaneous flushing, sweating, bronchospasm, colicky abdominal pain, diarrhea, and right-sided cardiac valvular fibrosis
