

Neurodegenerative disorders-2

Manar Hajeer, MD, FRCPath

University of Jordan, School of medicine

Different diseases

- ▶ **Involving the cortex**>>>> cognitive abnormalities of memory, behavior and language >>>> dementia >>>>>ALZHEIMER DISEASE (AD) , FRONTOTEMPORAL DEMENTIA (FTD), PICK DISEASE (SUBTYPE OF FTD)
- ▶ **Involving the basal ganglia** >>>>> **movement disorders** >>>>>**hypokinesia (PARKINSON DISEASE) or hyperkinesia (HUNTINGTON DISEASE)**
- ▶ **Involving the cerebellum** >>>> ataxia >>> (SPINOCEREBELLAR ATAXIA)
- ▶ **Involving the motor system** >>> difficulty swallowing and respiration with muscle weakness >> (AMYOTROPHIC LATERAL SCLEROSIS)

**Silence is golden
when you can't
think of a good
answer.**

Parkinson Disease (PD)

- ▶ A hypokinetic movement disorder that is caused by loss of dopaminergic neurons from the substantia nigra.
- ▶ Second most common neurodegenerative disorder after Alzheimer's disease
- ▶ *Parkinsonism* is a clinical syndrome: tremor, rigidity, bradykinesia, and instability.
- ▶ Parkinsonism: any damage of dopaminergic neurons, which project from the substantia nigra to the striatum (control of motor activity).

- ▶ Parkinsonism: induced by drugs such as dopamine antagonists or toxins that selectively injure dopaminergic neurons

Pathogenesis

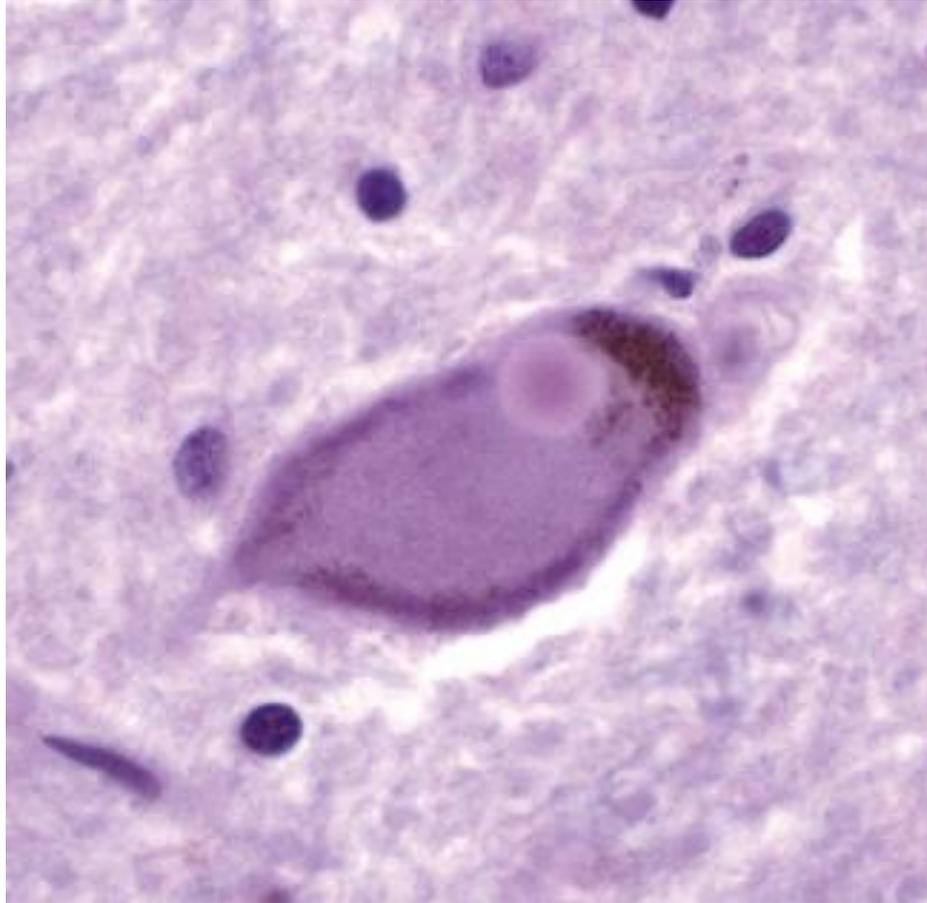

- ▶ protein accumulation and aggregation , mitochondrial abnormalities and neuronal loss in the substantia nigra and elsewhere in the brain
- ▶ Abnormal protein and organelle clearance due to **defects in autophagy and lysosomal degradation**
- ▶ Clue and diagnostic feature: Lewy body (neuronal inclusions containing *α-synuclein*, a protein involved in synaptic transmission)
- ▶ Most cases sporadic, some are autosomal dominant (mutation of *α-synuclein gene*)

Normal
substantia
nigra

Depigmented
substantia nigra
in idiopathic
Parkinson
disease

body in a

nigra stains
pink.

MORPHOLOGY

- ▶ Pallor of the substantia nigra and locus ceruleus
- ▶ Loss of the pigmented neurons in these regions.
- ▶ Gliosis.
- ▶ Lewy bodies in neurons (single or multiple, cytoplasmic, eosinophilic, round to elongated inclusions)
- ▶ Lewy neurites: dystrophic neurites that also contain aggregated α -synuclein
- ▶ Immunohistochemical staining for α -synuclein (for subtle lewy bodies).
- ▶ With progression changes can appear in: medulla, pons, amygdala, and the cerebral cortex (+Lewy body dementia LBD)

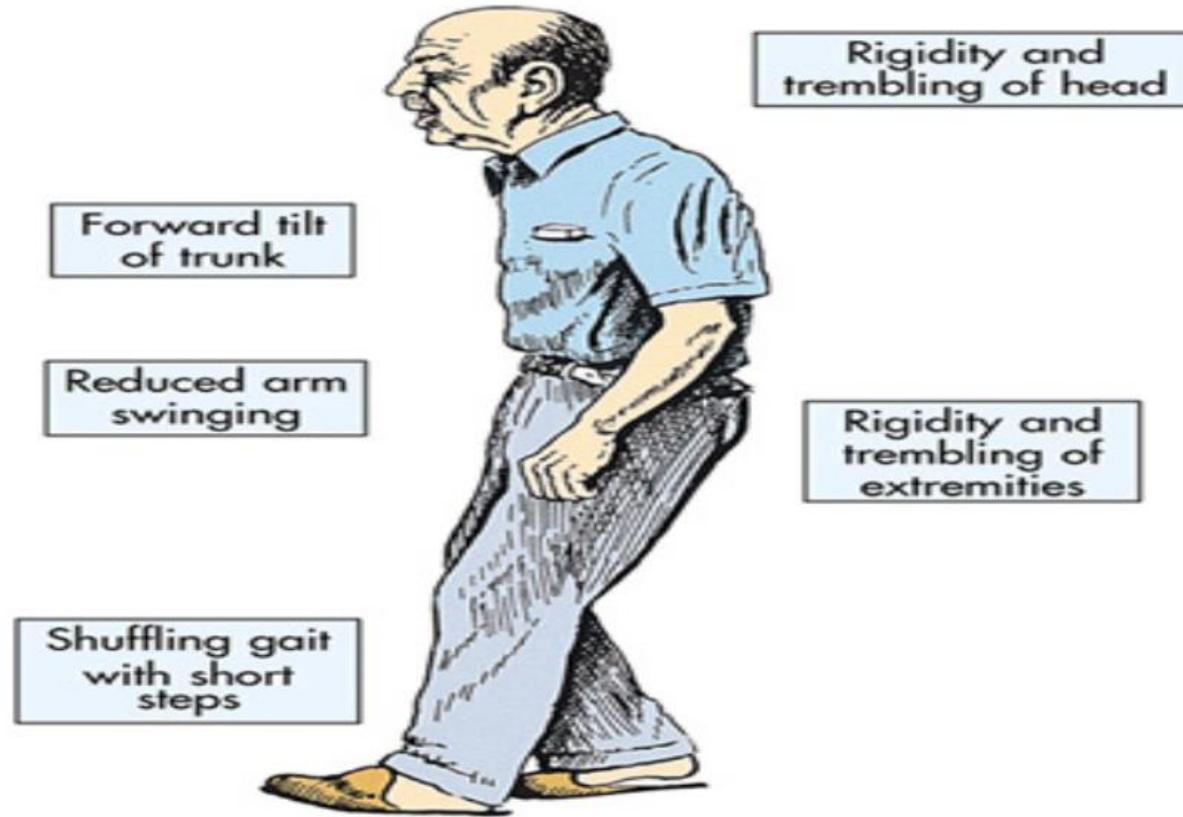

Clinical Features

- ▶ Progresses over 10 to 15 years
- ▶ Eventually producing severe motor slowing or near immobility.
- ▶ Death due to aspiration pneumonia or trauma from falls caused by postural instability.
- ▶ Initially respond to L-dihydroxyphenylalanine (L-DOPA), but this treatment does not slow disease progression or reverse morphologic findings
- ▶ Over time, L-DOPA becomes less effective
- ▶ Another Tx: deep brain stimulation

SYMPTOMS

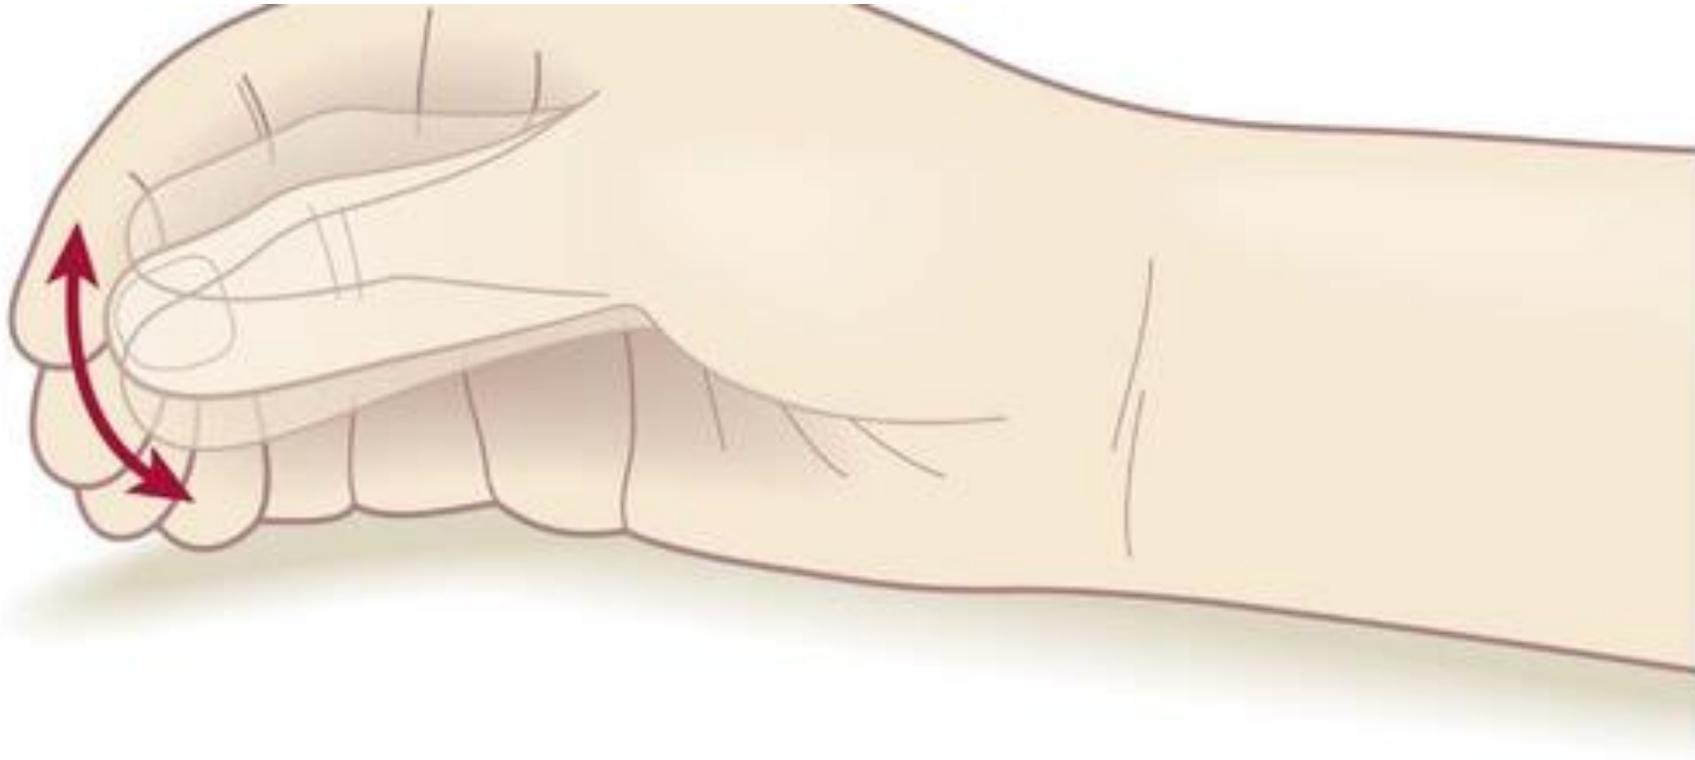

- ▶ **Tremor.** involuntary shaking, usually at rest and disappears with movement, begins in a limb, often in the hands or fingers. Patients might rub their thumb and forefinger back-and-forth (pill-rolling tremor.)
- ▶ **Slowed movement (bradykinesia) :** steps may become shorter, difficult to get out of a chair. Patients drag their feet as they try to walk.(Shuffling , festinating gate)
- ▶ **Rigid muscles.** The stiff muscles can be painful and limit the range of motion.
- ▶ **Impaired posture and balance.** stooped posture (leaning forward), and balance problems
- ▶ **Loss of automatic movements.:** decreased ability to perform unconscious movements, including blinking, smiling or swinging arms during walking
- ▶ **Speech changes.** Patients might speak softly, quickly, slur or hesitate before talking.
- ▶ **Writing changes.** It may become hard to write

- ▶ Diminished facial expressions (Masked facies)
- ▶ Stooped posture
- ▶ Slow voluntary movement
- ▶ Rigidity
- ▶ Pill rolling tremor
- ▶ Festinating gait= progressively shortened accelerated steps.

Stooped posture

Pill rolling tremor

Parkinson's Disease

Bradykinesia
(as seen in toe tapping)

+

Cogwheel Rigidity

Resting Tremor
(pill rolling tremor)

Other motor features:

Shuffling Gait

Mask-like Expression

Postural Instability

Huntington Disease

- ▶ Autosomal dominant movement disorder associated with degeneration of the striatum (caudate and putamen)
- ▶ Involuntary jerky movements of all parts of the body; writhing movements of the extremities .
- ▶ Progressive , death after an average 15 years
- ▶ Early cognitive symptoms (forgetfulness and thought and affective disorders, severe dementia).

Chorea

This is a genetic disorder which affects the functioning of the brain

Chorea is a medical condition and a type of movement disorder

Pathogenesis

- ▶ CAG trinucleotide repeat expansions in huntingtin protein gene located on 4p16.3 (Polyglutamine)
- ▶ Normal alleles contain 11 to 34 copies of the repeat.
- ▶ Disease-causing alleles, number of repeats is increased (may be hundreds)
- ▶ Larger numbers of repeats results in earlier-onset disease.
- ▶ Mutant protein is subject to proteolysis >>> fragments can form large intranuclear aggregates >>> toxic

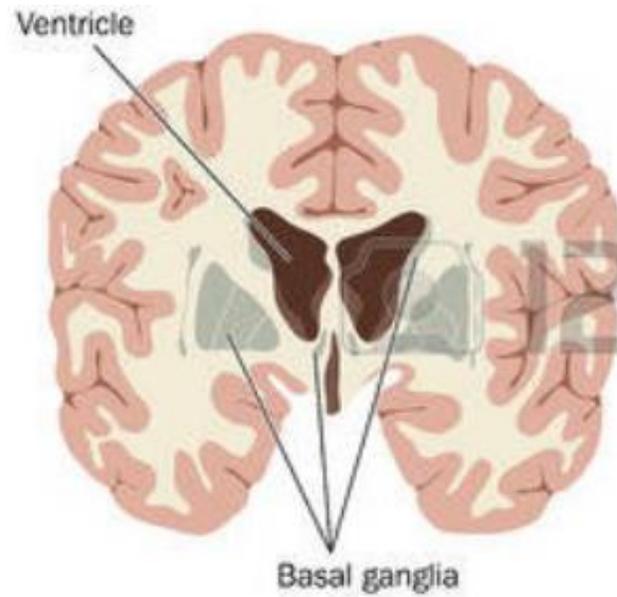

- ▶ Age of onset:40-50 years; related to the length of CAG repeats (more repeats; earlier age of onset)

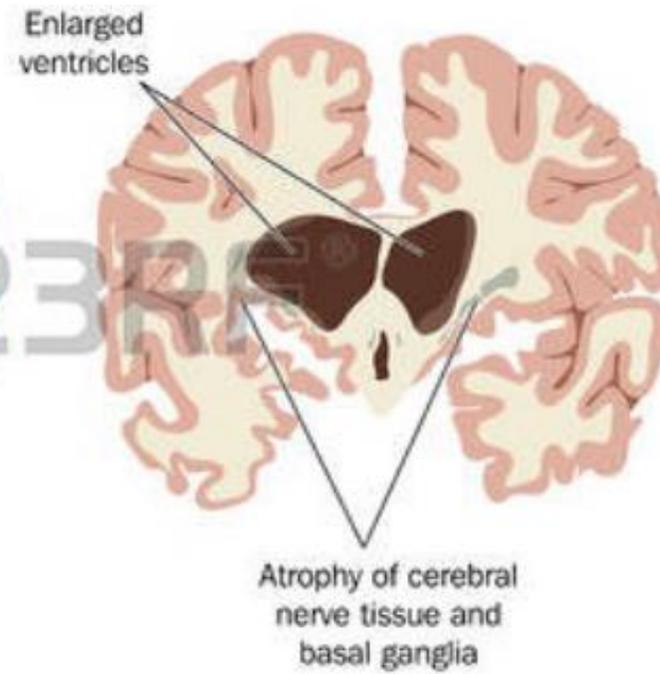

Morphology:

- ▶ Brain is small
- ▶ Striking atrophy of the caudate nucleus and the putamen
- ▶ Atrophy of globus pallidus
- ▶ Dilated lateral and third ventricles
- ▶ Severe loss of neurons from affected regions of the striatum + gliosis
- ▶ Spiny neurons that release γ -aminobutyric acid (GABA), enkephalin, dynorphin, and substance P are especially sensitive, disappearing early.
- ▶ Intranuclear inclusions (aggregates of ubiquitinated huntingtin protein)

Normal brain

Huntington's disease

- ▶ Several members of a large family are affected by the onset of decreasing mental function and motor coordination when they reach middle age. Their extremity movements are marked by choreoathetosis. Genetic testing reveals increased trinucleotide CAG repeats. Which of the following intracranial structures is most likely to appear grossly abnormal with radiologic imaging of these affected persons?
- ▶ A Caudate nucleus
- ▶ B Midbrain
- ▶ C Temporal lobe
- ▶ D Locus ceruleus
- ▶ E Spinal cord

- 
- ▶ A 66-year-old man is finding that he has more difficulty getting up and moving about for the past year. He is annoyed by a tremor in his hands, but the tremor goes away when he performs routine tasks using his hands. His friends remark that he seems more sullen and doesn't smile at them, but only stares with a fixed expression on his face. He has not suffered any loss of mental ability. Which of the following conditions is he most likely to have?
 - ▶ A Amyotrophic lateral sclerosis (ALS)
 - ▶ B Huntington disease
 - ▶ C Parkinson disease
 - ▶ D Niemann-Pick disease
 - ▶ E Tuberous sclerosis
